

Additive Noise Models: Identifiability Theorems, Learning Algorithms, Hidden Variables and Time Series

Behrad Moniri

Sharif University of Technology

bemoniri@ee.sharif.edu

Model Definition

We call the SCM, C , an additive noise model if each observed variable X_j is associated with a node j in a directed acyclic graph G , and the value of X_j is obtained as a function of its parents in G , plus independent additive noise N_j , i.e.

$$X_j = f_j(\mathbf{PA}_j) + N_j, \quad j = 1, \dots, p \quad (1)$$

with jointly independent variables N_j . We will assume that the noise variables have strictly positive density.

Causal Minimality

For those models with strictly positive density, causal minimality reduces to the condition that each function f_j is not constant in any of its arguments.

Identifiability: The Bivariate Case

Hoyer et al. (2009) proves the following theorem about the identifiability of bivariate additive noise models.

Theorem

An additive noise model with two variables, i.e., $X_1 = N_1$ and $X_2 = f(X_1) + N_2$, with $N_1 \perp\!\!\!\perp N_2$, is identifiable if it does not solve the following differential equation for all x_1, x_2 with $\nu''(x_2 - f(x_1))f'(x_1) \neq 0$:

$$\xi''' = \xi'' \left(-\frac{\nu''' f'}{\nu''} + \frac{f''}{f'} \right) - 2\nu'' f'' f' + \nu' f''' + \frac{\nu' \nu''' f'' f'}{\nu''} - \frac{\nu' (f'')^2}{f'},$$

Here $\xi := \log p_{X_1}$ and $\nu := \log p_{N_2}$ and we have skipped the arguments $x_2 - f(x_1)$, x_1 , and x_1 for ν , ξ , and f and their derivatives, respectively.

Corollary

Gaussian Noise: Assume that $\nu''' = \xi''' = 0$ everywhere. If a backward model exists, then f is linear.

Corollary

Assume that $f(x) = x$ and $p_x(x) = e^{-x-e^{-x}}$ and $p_n(n) = e^{-n-e^{-n}}$. With $p_y(y) = e^{-y-2\log(1+e^y)}$, $\tilde{p}_n(\tilde{n}) = e^{-2\tilde{n}-e^{-\tilde{n}}}$ and $g(y) = \log(1 + e^{-y})$, one obtains:

$$p(x, y) = p_n(y - f(x))p_x(x) = \tilde{p}_n(x - g(y))p_y(y)$$

so the model is not identifiable.

Identifiability: From Bivariate to Multivariate

Definition

Consider an ANM with p variables. We call this SCM a *restricted additive noise model* if for all $j \in \mathbf{V}$, $i \in \mathbf{PA}_j$ and all sets $\mathbf{S} \subseteq \mathbf{V}$ with $\mathbf{PA}_j \setminus \{i\} \subseteq \mathbf{S} \subseteq \mathbf{ND}_j \setminus \{i, j\}$, there is an $x_{\mathbf{S}}$ with $p_{\mathbf{S}}(x_{\mathbf{S}}) > 0$, such that

$$\left(f_j(x_{\mathbf{PA}_j \setminus \{i\}}, X_i), P(X_i | X_{\mathbf{S}} = x_{\mathbf{S}}), P(N_j) \right)$$

satisfies the bivariate identifiability conditions.

We assume that the noise variables to have non-vanishing densities and the functions f_j are three times differentiable.

Identifiability: The Multivariate Case

Peters et al. (2014) proves a very interesting theorem. This theorem states how we can generalize a bivariate identifiability to the multivariate case, in this case ANM identifiability.

Theorem

Let X_1, \dots, X_p be generated by a restricted additive noise model with graph G_0 and assume that $P_{\mathbf{X}}$ satisfies causal minimality with respect to G_0 , i.e., the functions f_j are not constant. Then, G_0 is identifiable from the joint distribution.

Identifiability: Post Non Linear (PNL) Models

Definition

PNL Models are introduced in Zhang and Hyvärinen (2009). A PNL is an SCM where each expresses each variable X_i as

$$X_i = g_i(f_i(\mathbf{PA}_i) + N_i), \quad i = 1, \dots, n$$

Theorem (Bivariate Identifiability)

Assume that $x_2 = f_2(f_1(x_1) + e_2)$ and $x_1 = g_2(g_1(x_2) + e_1)$. Densities and nonlinear functions are three times differentiable. We then have the following equation for every (x_1, x_2) satisfying $\eta'' h' \neq 0$:

$$t_1 = g_2^{-1}(x_1), \quad z_2 = f_2^{-1}(x_2), \quad h = f_1 \circ g_2, \quad h_1 = g_1 \circ f_2$$

$$\eta_1(t_1) = \log p_{t_1}(t_1) \quad \eta_2(e_2) = \log p_{e_2}(e_2)$$

$$\eta_1''' - \frac{\eta_1'' h''}{h'} = \left(\frac{\eta_2' \eta_2'''}{\eta_2''} - 2\eta_2'' \right) \cdot h' h'' - \frac{\eta_2'''}{\eta_2''} \cdot h' \eta_1'' + \eta_2' \cdot \left(h''' - \frac{h''^2}{h'} \right)$$

and h_1 depends on η_1 , η_2 , and h in the following way:

$$\frac{1}{h_1'} = \frac{\eta_1'' + \eta_2'' h'^2 - \eta_2' h''}{\eta_2'' h'}$$

	p_{e_2}	$p_{t_1} (t_1 = g_2^{-1}(x_1))$	$h = f_1 \circ g_2$	Remark
I	Gaussian	Gaussian	linear	h_1 also linear
II	log-mix-lin-exp	log-mix-lin-exp	linear	h_1 strictly monotonic, and $h'_1 \rightarrow 0$, as $z_2 \rightarrow +\infty$ or as $z_2 \rightarrow -\infty$
III	log-mix-lin-exp	one-sided asymptotically exponential (but not log-mix-lin-exp)	h strictly monotonic, and $h' \rightarrow 0$, as $t_1 \rightarrow +\infty$ or as $t_1 \rightarrow -\infty$	—
IV	log-mix-lin-exp	generalized mixture of two exponentials	Same as above	—
V	generalized mixture of two exponentials	two-sided asymptotically exponential	Same as above	—

Figure: All unidentifiable cases with the assumptions made above

Learning Algorithms : Score Based Method

- The score proposed by Peters et al. (2014) and Nowzohour and Bühlmann (2016):

$$\hat{G} = \operatorname{argmin}_G \sum_{i=1}^n \operatorname{DM}(res_i^{G, \operatorname{RM}}, res_{-i}^{G, \operatorname{RM}}) + \lambda \# \text{edges}$$

- DM = Dependence Method RM = Regression Method
- Idea : Noises are independent
- They do not prove (or even claim) that the minimizing of the above score is a consistent estimator for the correct DAG.
- Learning Algorithm: Greedy DAG Search or Brute Force (Only for small graphs)

Learning Algorithms : RESIT Algorithm

- First proposed in Peters et al. (2014)
- Assumption : Multivariate ANM + Causal Sufficiency
- Idea : X_i is sink $\iff N_i \perp\!\!\!\perp \mathbf{X} \setminus \{X_i\}$
- There are two stages in the algorithm:
 - Stage 1 : Finding a causal order
 - Stage 2 : Estimating DAG by removing edges
- Number of Tests (Less than PC)
 - Stage 1 : $O(n^2)$
 - Stage 2 : $O(n)$

Learning Algorithms : RESIT Algorithm

Algorithm 1 Regression with subsequent independence test (RESIT)

```

1: Input: I.i.d. samples of a  $p$ -dimensional distribution on  $(X_1, \dots, X_p)$ 
2:  $S := \{1, \dots, p\}, \pi := []$ 
3: PHASE 1: Determine topological order.
4: repeat
5:   for  $k \in S$  do
6:     Regress  $X_k$  on  $\{X_i\}_{i \in S \setminus \{k\}}$ .
7:     Measure dependence between residuals and  $\{X_i\}_{i \in S \setminus \{k\}}$ .
8:   end for
9:   Let  $k^*$  be the  $k$  with the weakest dependence.
10:   $S := S \setminus \{k^*\}$ 
11:   $\text{pa}(k^*) := S$ 
12:   $\pi := [k^*, \pi]$  ( $\pi$  will be the topological order, its last component being a sink)
13: until  $\#S = 0$ 
14: PHASE 2: Remove superfluous edges.
15: for  $k \in \{2, \dots, p\}$  do
16:   for  $\ell \in \text{pa}(\pi(k))$  do
17:     Regress  $X_{\pi(k)}$  on  $\{X_i\}_{i \in \text{pa}(\pi(k)) \setminus \{\ell\}}$ .
18:     if residuals are independent of  $\{X_i\}_{i \in \{\pi(1), \dots, \pi(k-1)\}}$  then
19:        $\text{pa}(\pi(k)) := \text{pa}(\pi(k)) \setminus \{\ell\}$ 
20:     end if
21:   end for
22: end for
23: Output:  $(\text{pa}(1), \dots, \text{pa}(p))$ 

```

Confounder Detection in The Bivariate Case

$$\begin{cases} X = f(T) + N_X \\ Y = g(T) + N_Y \end{cases}$$

Naive Method: Dimension Reduction

$$\hat{T}_k = \operatorname{argmin}_{t \in [0,1]} \|(X_k, Y_k) - \mathbf{s}(t)\|_2$$

find $\hat{\mathbf{s}}$ that minimizes $\sum_{k=1}^n \|(X_k, Y_k) - \mathbf{s}(\hat{T}_k)\|_2$. Then test the independence of noise variables

Confounder: ICAN Algorithm

Algorithm 1 Identifying Confounders using Additive Noise Models (ICAN)

```

1: Input:  $(X_1, Y_1), \dots, (X_n, Y_n)$  (normalized)

2: Initialization:
3: Fit a curve  $\hat{\mathbf{s}}$  to the data that minimizes  $\ell_2$  distance:  $\hat{\mathbf{s}} := \operatorname{argmin}_{\mathbf{s} \in \mathcal{S}} \sum_{k=1}^n \operatorname{dist}(\mathbf{s}, (X_k, Y_k))$ .

4: repeat
5:   Projection:
6:    $\hat{T} := \operatorname{argmin}_T \operatorname{DEP}(\hat{N}_X, \hat{N}_Y) + \operatorname{DEP}(\hat{N}_X, T) + \operatorname{DEP}(\hat{N}_Y, T)$  with  $(\hat{N}_{X,k}, \hat{N}_{Y,k}) = (X_k, Y_k) - \hat{\mathbf{s}}(T_k)$ 
7:   if  $\hat{N}_X \perp\!\!\!\perp \hat{N}_Y$  and  $\hat{N}_X \perp\!\!\!\perp \hat{T}$  and  $\hat{N}_Y \perp\!\!\!\perp \hat{T}$  then
8:     Output:  $(\hat{T}_1, \dots, \hat{T}_n)$ ,  $\hat{u} = \hat{\mathbf{s}}_1$ ,  $\hat{v} = \hat{\mathbf{s}}_2$ , and  $\frac{\operatorname{Var} \hat{N}_X}{\operatorname{Var} \hat{N}_Y}$ .
9:     Break.
10:  end if

11: Regression:
12: Estimate  $\hat{\mathbf{s}}$  by regression  $(X, Y) = \hat{\mathbf{s}}(\hat{T}) + \hat{\mathbf{N}}$ . Set  $\hat{u} = \hat{\mathbf{s}}_1$ ,  $\hat{v} = \hat{\mathbf{s}}_2$ .

13: until  $K$  iterations

14: Output: Data cannot be fitted by a CAN model.
```

- The Naive method does not work even in simple cases.
- ICAN was first introduced in Janzing et al. (2009).
- Idea: Minimizing dependence instead of the l_2 norm.
- Proof of consistency only for the low noise regime. The algorithm seems to work in large noise regime as well.

Time Series : TiMINo

Definition

Consider a time series $\mathbf{X}_t = (X_t^i)_{i \in V}$. We say the time series satisfies a *TiMINo* if there is a $p > 0$ and if $\forall i \in V$ there are sets

$\mathbf{PA}_0^i \subseteq X^{V \setminus \{i\}}, \mathbf{PA}_k^i \subseteq X^V$, s.t. $\forall t$

$$X_t^i = f_i((\mathbf{PA}_p^i)_{t-p}, \dots, (\mathbf{PA}_1^i)_{t-1}, (\mathbf{PA}_0^i)_t, N_t^i), \quad (2)$$

with N_t^i (jointly) independent and for each i , N_t^i identically distributed in t and the full time graph is acyclic.

Peters et al. (2013)

Time Series : TiMINo

Algorithm 1 TiMINo causality

- 1: **Input:** Samples from a d -dimensional time series of length T : $(\mathbf{X}_1, \dots, \mathbf{X}_T)$, maximal order p
 - 2: $S := (1, \dots, d)$
 - 3: **repeat**
 - 4: **for** k in S **do**
 - 5: Fit TiMINo for X_t^k using $X_{t-p}^k, \dots, X_{t-1}^k, X_{t-p}^i, \dots, X_{t-1}^i, X_t^i$ for $i \in S \setminus \{k\}$
 - 6: Test if residuals are indep. of $X^i, i \in S$.
 - 7: **end for**
 - 8: Choose k^* to be the k with the weakest dependence. (If there is no k with independence, break and output: “I do not know - bad model fit”).
 - 9: $S := S \setminus \{k^*\}; \text{ pa}(k^*) := S$
 - 10: **until** $\text{length}(S) = 1$
 - 11: For all k remove all parents that are not required to obtain independent residuals.
 - 12: **Output:** $(\text{pa}(1), \dots, \text{pa}(d))$
-

TiMINo causality has to be provided with a fitting method. e.g. VAR fitting, generalized additive models (gam) and GP regression.

Time Series : Granger Causality vs. TiMINo

- TiMINo allows instantaneous effects.
- Shifted Time Series ($\tilde{X}_t^i = X_{t-l_i}^i$) for example in fMRI Data.
There might be causal relations backwards in time and Granger Causality might fail in these cases. In TiMINo, the summary graph is identifiable.
- in some cases, TiMINo output is "Can't Decide"

- a simple case with confounder:

$$\begin{cases} X_t = 0.8X_{t-1} + 0.3N_{X,t} \\ Y_t = 0.4Y_{t-1} + (X_{t-1} - 1)^2 + 0.3N_{Y,t} \\ Z_t = 0.4Z_{t-1} + 0.5\cos(Y_{t-1}) + \sin(Y_{t-1}) + 0.3N_{Z,t} \end{cases}$$
